Dimensional properties of the harmonic measure for a random walk on a hyperbolic group

Vincent Le Prince

1st February 2008

Abstract: This paper deals with random walks on isometry groups of Gromov hyperbolic spaces, and more precisely with the dimension of the harmonic measure ν associated with such a random walk. We first establish a link of the form $\dim \nu \leq h/l$ between the dimension of the harmonic measure, the asymptotic entropy h of the random walk and its rate of escape l. Then we use this inequality to show that the dimension of this measure can be made arbitrarily small and deduce a result on the type of the harmonic measure.

Keywords: ergodic theory, random walk, hyperbolic group, harmonic measure, entropy.
MSC: 60J15, 20F67, 28D20, 28A78.

Introduction

Let (X,d) be a hyperbolic space and G a non-elementary subgroup of its isometry group acting properly discontinuously. Given a probability measure μ on G, we define the associated random walk (x_n) by $x_n = h_1 \cdots h_n$, h_i being μ-distributed independent random variables. Under some hypotheses on μ, we can describe the asymptotic behaviour of this random walk: if the support of μ generates G then almost all trajectories converge to an element x_∞ of the hyperbolic boundary ∂X of X, whose distribution is called the harmonic measure and denoted by ν; if moreover μ has a finite first moment then $(\partial X, \nu)$ coincides with the Poisson boundary of the random walk ([11], see Section 1 for the definitions and details).

On the boundary of a tree we can define a metric by :

$$dist(\xi_1,\xi_2) = e^{-(\xi_1|\xi_2)} \ ;$$

$(\xi_1|\xi_2)$ being the Gromov product (here the length of the common part) of ξ_1 and ξ_2. In the general case, this formula doesn't define a metric, but there exists a family of metrics $(d_a)_{1<a<a_0}$ on ∂X having the same properties. We shall consider in this article the relations between this metric structure and the harmonic measure. More precisely we are interested in the Hausdorff dimension of this measure and hence in its type. Our main result will be the fact that the harmonic measure is not necessary absolutely continuous with respect to the Hausdorff measure on the boundary but can be singular. This question has been considered for random walks on $SL(2,\mathbb{R})$ related to continued fractions ([1], [14]) and in some others contexts (e.g. [20]).

Note that in some situations like for the nearest neighbor random walks on finitely generated free groups (see [6], [17], [16]) or on finite free products of finite groups ([18]), this harmonic measure can be explicitely computed, but in general this is not the case. Whereas in the above cited articles combinatorial methods, based on a description of the hyperbolic boundary as a set of infinite words, are used, we shall use geometrical methods.

Let us now describe more precisely the contents of this paper.
The following relation between the dimension of ν, the rate of escape l of the random walk and

its asymptotic entropy h (see Section 1 for the definitions) was established in the case of trees in [10] and [16] :

$$\dim \nu = \frac{h}{l} \ . \tag{1}$$

Section 2 is devoted to an extension of this result to the case of the subgroup of isometries of a hyperbolic group (see Prop. 2.1 for a more precise statement):

$$\dim \nu \leq \frac{1}{\log a} \ \frac{h}{l} \ , \tag{2}$$

a being the parameter used for the choice of the metric on the hyperbolic boundary.
Then we want to show that the dimension of this measure can be arbitrarily small. For this purpose we construct in Section 4 a sequence (μ_k) of probability measures such that, denoting the asymptotic entropy and the rate of escape associated with μ_k respectively by $h(G, \mu_k)$ and $l(G, \mu_k)$, we have

$$\lim_{k \to +\infty} \frac{h(G, \mu_k)}{l(G, \mu_k)} = 0 \ .$$

To show this property we will need a formula to estimate the rate of escape; this formula is stated in Section 3. Combined with the previous upper bound on the dimension, this gives us the following result.

Theorem 5.1 *Let G be a subgroup of the group of isometries of a hyperbolic space (X, d) acting properly discontinuously and which is not elementary. For every $\epsilon > 0$ there exists on G a symmetric probability measure μ with a finite first moment, whose support generates G, and which has the following property: the pointwise dimension of the harmonic measure ν associated with (G, μ) is ν-almost surely smaller than ϵ.*

In the case where X is the Cayley graph of the hyperbolic group G equipped with the word metric (w.r.t. a certain system of generators S), the dimension of the boundary ∂G is equal to the growth $v(G, S)$ of G (w.r.t. the same S). Moreover the Hausdorff measure is then finite and non zero. Theorem 5.1 implies that the harmonic measure can be singular with respect to this Hausdorff measure (Corollary 5.1).

Two other natural questions on the dimension are the following.
The first, which in some sense is the opposite to the one we consider, is the question of knowing whether the harmonic measure can be of maximal dimension. In the case where X is the Cayley graph of G, the support of the harmonic measure is ∂X. The dimension of ∂X is, denoting by v the growth of G and working with the distance d_a on ∂X, equal to $v_a(G) = v / \log a$ ([3], see Section 1). We have a fundamental relation between h, l an v (see [21]):

$$h \leq lv. \tag{3}$$

In view of the inequality (2), the question of the maximality of the dimension of the harmonic measure is then related to the question raised in [21] of knowing whether the quotient h/l can be maximal, i.e. equal to v.
The second is the question of the positivity of the dimension of the harmonic measure. Under the hypothesis stated in the first paragraph of this introduction, the Poisson boundary is not trivial. A well-known fact of the theory of Poisson boundaries is that this non-triviality is equivalent to the asymptotic entropy h being strictly positive ([12]). So in the case of a tree the formula $\dim \nu = h/l$ implies that the dimension of the harmonic measure is strictly positive. But with only the inequality (2) we can't conclude. In [13] a similar result (i.e. positivity of the dimension of the harmonic measure) is proven in the case of the Brownian motion on a Riemannian manifold with pinched negative sectional curvature.

1 Preliminaries and notations

1.1 Hyperbolic spaces

We will need a rather complete description of some aspects of the geometry of hyperbolic spaces ([9]), which we recall there. Our main references are [4] and [8].

Definition

Let (X, d) be a proper geodesic metric space. Let o be a point in X; we define the Gromov product (w.r.t. o) on X^2 :

$$(x|y)_o = \frac{1}{2}[d(o,x) + d(o,y) - d(x,y)] \ .$$

We call (X, d) a δ-hyperbolic space if this product satisfies, for all x, y, z, o in X,

$$(x|z)_o \geq \min\{(x|y)_o, (y|z)_o\} - \delta \ . \tag{4}$$

We say that X is hyperbolic if there exists δ such that X is δ-hyperbolic. An important class of hyperbolic spaces is the one of word hyperbolic groups. One can define on the Cayley graph of a finitely generated group G (w.r.t. a symmetric system of generators S) a metric which is the word metric (w.r.t. S) in restriction to G and which makes every edge isometric to the segment $[0, 1]$. A finitely generated group G is said to be hyperbolic when its Cayley graph equipped with this metric is a hypaerbolic space (which doesn't depend on the choice of S).
We fix for the sequel a δ-hyperbolique space (X, d) equipped with a point o and we denote the Gromov product of x and y w.r.t. o by $(x|y)$.

Hyperbolic boundary

We recall that a geodesic (resp. geodesic ray, resp. geodesic segment) in X is an isometry from $\mathbb{R}$ (resp. $[0, \infty[$, resp. $[a, b]$) to X, as well as the image of such an isometry.
Two geodesic rays σ_1 and σ_2 in X are said to be equivalent ($\sigma_1 \sim \sigma_2$) if there exists a constant D such that for all t, $d(\sigma_1(t), \sigma_2(t)) \leq D$. The hyperbolic boundary is defined as the quotient of the set of geodesic rays by this equivalence relation.
One can extend the Gromov product to $X \cup \partial X$. The relation (4) remains true. One can then define a topology on $X \cup \partial X$, which makes $X \cup \partial X$ be a compactification of X, by taking for each point ξ in ∂X as a base of neighborhood the sets

$$\big\{x \in X \cup \partial X : (\xi|x) > R\big\} \ , \ (R > 0).$$

A sequence (x_n) converges to an element ξ in ∂X if and only if

$$\lim_{n\to\infty} (\xi|x_n) = +\infty \ .$$

In particular, if σ is a geodesic ray, $\sigma(t)$ converges, when t goes to infinity, to the equivalence class of σ in ∂X, which we denote by $\sigma(+\infty)$. Moreover, if (x_n) converges to x and (y_n) to y, we have (see [8])

$$(x|y) \leq \liminf_n (x_n|y_n) \leq (x|y) + 2\delta \ . \tag{5}$$

The action of the isometry group on X extends to a continuous action on the boundary.
When X is the Cayley graph of a hyperbolic group G, we shall write ∂G instead of ∂X.

Metric on the boundary

On the boundary of a tree we can define a metric by :

$$dist(\xi_1, \xi_2) = e^{-(\xi_1|\xi_2)} \ ;$$

In the general case, this formula doesn't define a metric, but there exists a family of metrics $(d_a)_{1<a<a_0}$ on $X \cup \partial X$ (see [4], ch. 11). We fix such a a for the sequel. We will need the following property, which shows the analogy with the case of the trees (see [4]):

Proposition 1.1. *There exists a constant* $\lambda > 0$ *such that*

- $\forall x, y \in X \cup \partial X,\ d_a(x, y) \leq \lambda a^{-(x|y)}$ *;*
- $\forall x, y \in \partial X,\ d_a(x, y) \geq \lambda^{-1} a^{-(x|y)}$ *.*

Note that the topology induced by this metric on $X \cup \partial X$ coincides with the one previously defined.

Limit set of a subgroup of isometries

Let G a subgroup of isometries acting properly discontinuously on (X, d). A reference for this part is [2].

Definition 1.1. *The set of accumulation points in* ∂X *of the* G*-orbit of a point* x *in* X *doesn't depend on the point* x*. We call it the limit set of the group* G *denoted by* Λ_G*.*

In the case of a hyperbolic group G acting on its Cayley graph, $\Lambda_G = \partial G$. This limit set will be the support of the harmonic measure; we need some of its properties.

Definition 1.2. *The group* G *is said to be elementary if* Λ_G *consists of at most two elements.*

If G is non-elementary, Λ_G is uncountable.

Definition 1.3. *Let* g *be an isometry in* X*. This element is said to be hyperbolic if* $(g^n o)_{n \in \mathbb{Z}}$ *is a quasi-geodesic ; which means that there exists two constants* λ *and* c *such that for all* n *and* m *in* $\mathbb{Z}$*,*

$$\lambda^{-1}|n-m| - c \leq d(g^n o, g^m o) \leq \lambda|n-m| + c \ .$$

Proposition 1.2. *Let* η *be a* (λ, c)*-quasi geodesic. Then* $\eta(t)$ *admits limits* $\eta(\pm\infty)$ *when* t *goes to* $\pm\infty$*. If* σ *is a geodesic with endpoints* $\sigma(\pm\infty) = \eta(\pm\infty)$*, then the images of* σ *and* η *lie at a finite Hausdorff distance* K *from each other,* K *depending only on* λ*,* c *and* δ*.*

In particular if an isometry g is hyperbolic, then there exists g^+ and g^- in ∂X such that $(g^n o)$ goes to g^+ and g^- when n go respectively to plus or minus infinity. In fact for all x in X, the sequences $(g^n x)$ converge to the same limits. The points g^+ and g^- are fixed points for g, which are said to be respectively attractive and repulsive.

Proposition 1.3. *([2]) A non-elementary group* G *contains hyperbolic elements.*

An important property of the limit set is its minimality (see [2]).

Proposition 1.4. *(Gromov) Assume* G *to be non-elementary. Then every non-void* G*-invariant compact set in* ∂X *contains* Λ*. In other words,* Λ *is the only minimal set.*

This has as a consequence :

Proposition 1.5. *Assume G to be non-elementary. Let U be an open set in ∂X which intersects Λ. Then we have :*

$$\partial X = \bigcup_{g\in G} gU \ ;$$

and since ∂X is compact : there exists a finite set of elements $g_1, \cdots, g_r$ in G such that

$$\partial X = \bigcup_{1\leq i\leq r} g_i U \ . \tag{6}$$

1.2 Random walk

We fix in this part a subgroup G of the group of isometries of (X, d) acting properly discontinuously and which is non-elementary.

Definition

Let μ be a probability measure on G. The random walk on G determined by the measure μ is the Markov chain $\boldsymbol{x} = (x_n)_{n\geq 0}$ with transition probabilities

$$p(x, y) = \mu(x^{-1}y)$$

and starting at $x_0 = e$. The position x_n at time $n \geq 1$ of the random walk is given by

$$x_n = h_1 \cdots h_n \ ;$$

$(h_n)_{n\geq 1}$ being a sequence of independent μ-distributed random variables. We call the h_n the increments and (x_n) the trajectory of the random walk. We note $\mathbb{P}$ the distribution of $\boldsymbol{x}$ in $G^{\mathbb{N}}$ and T the shift in $G^{\mathbb{N}}$.

The Markov operator P associated to the random walk is then:

$$Pf(x) = \sum_{g\in G} \mu(g) f(xg) \ .$$

We say that a function f on G is μ-harmonic if it satisfies $Pf = f$.

Poisson boundary and harmonic measure

The behaviour of the paths of the random walk is described by the following:

Proposition 1.6. *([11]) Assume that the support of the measure μ generates G. Then the random walk $(x_n o)$ associated to μ converges $\mathbb{P}$-almost surely to an element x_∞ in ∂X.*

We denote by *bnd* the map (defined on a set of $\mathbb{P}$-measure one) from $G^{\mathbb{N}}$ to ∂X which associate x_∞ to $\boldsymbol{x} = (x_n)$ and we note ν the distribution of x_∞, which we call the harmonic measure. Note that we have $\nu = bnd(\mathbb{P})$ and that *bnd* is G-equivariant.

Let us recall that if G, equipped with a measure μ, acts on a space Y with a measure m, the convolution $\mu * m$ of m by μ is defined by : for all continuous bounded function f ,

$$\int_Y f(y) d(\mu * m)(y) = \int_{G\times Y} f(gy) d\mu(g) dm(y) \ .$$

We say that a measure is μ-stationary if $\mu * \nu = \nu$.

The measure ν is μ-stationary. If we assume in addition that μ has a finite first moment, that is to say

$$\sum_{g\in G} \mu(g)d(o,go) < +\infty ,$$

then $(\partial X,\nu)$ is in fact the Poisson boundary associated to (G,μ)([11]); which means that every μ-harmonic bounded function f on G can be written :

$$f(g) = \int_{\partial X} F(g\xi)d\nu(\xi) ;$$

F being a bounded function on ∂X (for details on this notion, see [7] and [12]).
A first result on the type of the harmonic measure is that under previous hypothesis it doesn't have any atom. Besides if the support of μ generates G as a semi-group the support of the measure ν is the limit set Λ_G of G. This is a consequence of the minimality of this limit set and of stationnarity of ν, and can be established using Proposition 1.5 through the following lemma:

Lemma 1.1. *Let U be an open set in ∂X which intersects Λ_G. Then $\nu(U) > 0$.*

Proof. Let $\gamma_1,\cdots,\gamma_r \in G$ be such that

$$\Lambda_G \subset \bigcup_{1\leq i\leq r} \gamma_i U ;$$

and choose s such that $\gamma_1,\cdots,\gamma_r \in supp(\mu^s)$. Since ν is μ-stationnary we have

$$\nu(U) = \sum_{g\in supp(\mu^s)} \mu^s(g)\nu(gU) .$$

Hence if $\nu(U)=0$, we would have $\nu(\Lambda_G)=0$. □

Asymptotic quantities

Let μ be a probability measure on G having a finite first moment.
We write $|g| = d(o,go)$, and for a probability measure λ,

$$L(\lambda) := \sum_{g\in G} \lambda(g)|g| .$$

Denote by μ^n the n^{th} convolution of μ, which is the distribution of the position at time n of the random walk. The sequence $(L(\mu^n))_n$ is subadditive, which allows us to adopt the following definition :

Definition 1.4. *The limit of the sequence $\big(L(\mu^n)/n\big)_n$ is called rate of escape of the random walk $(x_n)_{n\geq 0}$ and denoted by $l(G,\mu)$.*

Moreover, μ having a finite first moment implies that the entropy

$$H(\mu) := \sum_g -\mu(g)\log(\mu(g))$$

of μ is finite. One can define in the same way the asymptotic entropy :

Definition 1.5. *The limit of the sequence $\big(H(\mu^n)/n\big)_n$ is called asymptotic entropy of the random walk $(x_n)_{n\geq 0}$ and denoted by $h(G,\mu)$.*

Using Kingman's subbadditive ergodic theorem, one gets ([5]) a $\mathbb{P}$-almost sure convergences:

$$-\frac{1}{n}\log(\mu^n(x_n)) \longrightarrow h(G,\mu) \quad \text{and} \quad \frac{|x_n|}{n} \longrightarrow l(G,\mu) .$$

If there is no ambiguity, we shall denote by h and l these two quantities. If in addition the support of μ generates G, both are positive (see [11]).

1.3 Dimension

Let (X,d) be a complete metric space. One defines the α-Hausdorff measure of a set $Z \subset X$ as

$$m_H(Z,\alpha) = \lim_{\epsilon \to 0} \inf \Big\{ \sum_{U \in \mathcal{G}_\epsilon} \big(diam(U)\big)^\alpha \Big\} \ ;$$

the infimum being taken over the covers $\mathcal{G}_\epsilon$ of Z by open sets of diameter at most ϵ. The usual Hausdorff dimension of Z is then

$$\dim_H(Z) = \inf \big\{ \alpha : m_H(Z,\alpha) = 0 \big\} = \sup \big\{ \alpha : m_H(Z,\alpha) = +\infty \big\} \ ; \tag{7}$$

When $m_H(X, \dim_H(X))$ is finite and non-zero, the function $Z \mapsto m_H(Z, \dim_H X)$ is, after normalization, a probability measure on X, called the Hausdorff measure.

Dimensions of measures

Let ν be a probability measure on (X,d). We define the Hausdorff dimension of ν as :

$$\dim_H \nu = \inf\{\dim_H Z : \nu(Z) = 1\} \ .$$

Remark 1.1. *The dimension of a measure characterizes to some extent its type. Indeed if λ is absolutely continuous w.r.t. ν, $\{Z : \nu(Z) = 1\} \subset \{Z : \lambda(Z) = 1\}$, so $\dim_H \lambda \leq \dim_H \nu$.*

To estimate the dimension of a set, and a fortiori of a measure, is usually not easy. We will have however a more direct way to estimate the dimension of a measure, introducing the (lower and upper) pointwise dimensions at a point x :

$$\underline{\dim}_P \nu(x) = \liminf_{r \to 0} \frac{\log \nu B(x,r)}{\log r} \quad \text{and} \quad \overline{\dim}_P \nu(x) = \limsup_{r \to 0} \frac{\log \nu B(x,r)}{\log r} \ .$$

Moreover this notion allows a more intuitive vision of the dimension of a measure : it can be regarded as the rate of decrease of the measure of balls. To relate the Hausdorff and pointwise dimensions, we will need a condition on the space (see [19], appendix 1).

Definition 1.6. *A metric space (X,d) is said to have finite multiplicity if there exist $K > 0$ and $\epsilon_0 > 0$ such that for all $\epsilon \in]0, \epsilon_0[$, there exists a cover of multiplicity K (i.e. in which every point belongs at most to K balls) of X by balls of radius ϵ.*

Proposition 1.7. *(see [19], appendix 1) Let (X,d) be a finite multiplicity space. Let ν be a probability measure on X. If there exists a constant d such that $\overline{\dim}_P \nu(x) \leq d$ ν-almost surely, then $\dim_H \nu \leq d$.*

If $\underline{\dim}_P \nu(x) \geq d$ ν-almost surely, we also have $\dim_H \nu \geq d$. A probability measure with a constant d such that $\underline{\dim}_P \nu(x) = \overline{\dim}_P \nu(x) = d$ ν-almost surely is said to be exact dimensionnal. All dimensions are equal in this case.

Case of the boundary of a hyperbolic group

We adopt the notations and hypotheses of the part 1.2. As we want to consider the question of the maximality of the dimension of the harmonic measure, it is natural to ask about the dimension of the limit set Λ_G, which supports this measure. We define the critical exposant of base a of G:

$$e_a(G) = \limsup_{R \to \infty} \frac{\log_a card\{g \in G : d(o, go) \leq R\}}{R} \ .$$

Proposition 1.8. *([3]) Under the hypothesis previously adopted and if in addition G is quasi-convex-cocompact (see [3] for a definition), then Λ_G has Hausdorff dimension $e_a(G)$ (with respect to the metric d_a).*

We don't want to explore this hypothesis of quasi-convex-cocompacity. We just note that in the case of a discrete group acting on the hyperbolic half-plane it coincides with the notion of convex-cocompacity; and we shall also use the fact that a hyperbolic group G acting on its Cayley graph has this property ([3]).

In Section 2, we bound from above the pointwise dimension of the harmonic measure. In order to obtain a result on the singularity of this measure with respect to the $e_a(G)$-Hausdorff measure, we need, in view of Proposition 1.7 and Remark 1.1, a finite multiplicity result on $(\partial X, d_a)$. Let us remark that when X is a tree, this is obvious because balls of the same diameter form a partition.

Theorem 1.1. *We assume that G is a hyperbolic group (X its Cayley graph). Then its hyperbolic boundary ∂G, equipped with the metric d_a, is of finite multiplicity.*

Proof. We first note that if two geodesic rays joining o with two points ξ_1 and ξ_2 of the boundary go through a same point x such that $d(o,x) = n$, then $(\xi_1|\xi_2) \geq n$ and so (see Proposition 1.1) $d_a(\xi_1, \xi_2) \leq \lambda a^{-n}$. Denote by W_n the set of words w of length n through which goes a certain geodesic ray starting at o ; and for each w in W_n let ξ_w be the limit point of such a ray. In view of our first remark, the set of all open balls $B(\xi_w, \lambda a^{-(n-1)})$, w in W_n, is a cover of the boundary.

We are now going to show that these covers are of finite multiplicity (uniformly bounded in n). Take $n > 0$ and set $\epsilon = a^{-n}$. Let ξ be a point in ∂X and let w be a word of length n through which goes a ray $[o, \xi[$. Now let $B(\xi_{w'}, \epsilon)$ be a ball of our cover in which lies ξ. Since $d_a(\xi, \xi_{w'}) < \epsilon$, $\lambda^{-1} a^{-(\xi|\xi_{w'})} < \lambda a^{-n}$; and so

$$(\xi|\xi_{w'}) \geq n - 2\log_a \lambda \ .$$

But we have

$$(w|w') \geq \min\left\{(w|\xi), (\xi|\xi_{w'}), (\xi_{w'}|w')\right\} - 2\delta \ ;$$

which yieds, as $(w|\xi) = (\xi_{w'}|w') = n$,

$$\begin{aligned}(w|w') &\geq \min\left\{n, (\xi|\xi_{w'})\right\} - 2\delta \\ &\geq n - 2\log_a \lambda - 2\delta \ .\end{aligned}$$

Since $(w|w') = n - \frac{1}{2}d(w, w')$, we deduce that

$$d(w, w') \leq 4\log_a \lambda + 4\delta \ .$$

But G is finitely generated, so there is only a finite number of w' of length n which distance from w is less than this constant, and this number doesn't depend on n. ☐

2 Relation between asymptotic quantities and pointwise dimension of the harmonic measure

In this section (X, d) is a δ-hyperbolic space, G a non-elementary subgroup of the group of isometries on X acting properly discontinuously. We also fix a measure μ on G with a finite first moment, and such that its support generates G as a semigroup. We shall use the notations of the previous section.

We have (see Section 1.2) $\mathbb{P}$-almost surely

$$\frac{(x_{n-1}|x_n)}{n} \longrightarrow l \quad \text{and} \quad -\frac{\log \mu^n(x_n)}{n} \longrightarrow h \ .$$

We define for $\epsilon > 0$ and N the set Ω_ϵ^N of trajectories such that for $n \geq N$,

- $(x_{n-1}|x_n) > (l-\epsilon)n$
- $-\log \mu^n(x_n) < (h-\epsilon)n.$

For $\eta > 0$ there exists then an integer $N_{\epsilon,\eta}$ such that

$$\forall N \geq N_{\epsilon,\eta} \ , \ \mathbb{P}(\Omega_\epsilon^N) > 1-\eta \ ;$$

we denote $\Omega_{\epsilon,\eta} = \Omega_\epsilon^{N_{\epsilon,\eta}}$. Denote also by $C_{\boldsymbol{x}}^n$ the set of trajectories whose n^{th} position coincides with x_n. Our demonstration is based on the following lemma :

Lemma 2.1. *([10]) There exist a set $\Lambda_{\epsilon,\eta} \subset \Omega_{\epsilon,\eta}$ with measure greater than $1-2\eta$, on which the quantity*

$$\frac{\mathbb{P}(C_{\boldsymbol{x}}^n \cap \Omega_{\epsilon,\eta})}{\mu^n(x_n)}$$

admits a strictly positive limit when n goes to infinity. In particular on this set we have

$$\limsup_n \frac{\log \mathbb{P}(C_{\boldsymbol{x}}^n \cap \Omega_{\epsilon,\eta})}{n} = \limsup_n \frac{\log \mu^n(x_n)}{n} \ .$$

We write, for $\xi \in \partial X$ and $r > 0$,

$$D(\xi, r) = \left\{\boldsymbol{x} : x_\infty \in B(\xi, r)\right\} \ .$$

In the next lemma we prove that if a trajectory is at time n in the same place as x_n, then its endpoint is not too far from x_∞.

Lemma 2.2. *Fix two strictly positive number η and ϵ. We have, for $\boldsymbol{x} \in \Lambda_{\epsilon,\eta}$ and $n \geq N_{\epsilon,\eta}$,*

$$C_{\boldsymbol{x}}^n \cap \Omega_{\epsilon,\eta} \subset D\left(x_\infty, \frac{2\lambda a^{-(l-\epsilon)(n+1)}}{1-a^{-(l-\epsilon)}}\right) \ ;$$

λ being the constant introduced in Proposition 1.1.

Proof. We fix $\boldsymbol{x} \in \Lambda_{\epsilon,\eta}$. Let $\boldsymbol{x'}$ be an element of $C_{\boldsymbol{x}}^n \cap \Omega_{\epsilon,\eta}$. Using the fact that $\boldsymbol{x'} \in \Omega_{\epsilon,\eta}$, we have, if n is big enough, $(x'_{n-1}|x'_n) > (l-\epsilon)n$; and thus, using Proposition 1.1,

$$d_a(x'_{n-1}, x'_n) \leq \lambda a^{-n(l-\epsilon)} \ .$$

So for $m > n$,

$$d_a(x'_n, x'_m) \leq \lambda a^{-(n+1)(l-\epsilon)} \sum_{k=0}^{m-1} a^{-k(l-\epsilon)} \ ;$$

which yields

$$d_a(x'_n, x'_\infty) \leq \frac{\lambda a^{-(n+1)(l-\epsilon)}}{1-a^{-(l-\epsilon)}} \ .$$

Since $\boldsymbol{x}$ clearly belongs to $C_{\boldsymbol{x}}^n \cap \Omega_{\epsilon,\eta}$, we get

$$d_a(x_\infty, x'_\infty) \leq \frac{2\lambda a^{-(n+1)(l-\epsilon)}}{1-a^{-(l-\epsilon)}} \ .$$

$\square$

The previous lemma gives us a bound from below of the ν-measure of the balls in ∂X and so we obtain :

Proposition 2.1. *For ν-almost all ξ,*

$$\overline{dim}_P \nu(\xi) \leq \frac{1}{\log a} \frac{h}{l} \ .$$

Proof. Let $\boldsymbol{x}$ be an element in $\Lambda_{\epsilon,\eta}$. We have

$$\overline{dim}_P \nu(x_\infty) = \limsup_{r \to 0} \frac{\log \nu B(x_\infty, r)}{\log r} = \limsup_{r \to 0} \frac{\log \mathbb{P} D(x_\infty, r)}{\log r} \ ;$$

and replacing r by $\frac{2\lambda a^{-(n+1)(l-\epsilon)}}{1-a^{-(l-\epsilon)}}$,

$$\overline{dim}_P \nu(x_\infty) = \limsup_{n \to \infty} \frac{\log \mathbb{P} D\Big(x_\infty, \frac{2\lambda a^{-(l-\epsilon)(n+1)}}{1-a^{-(l-\epsilon)}}\Big)}{-\log a \ (n+1)(l-\epsilon)} \ .$$

Using Lemma 2.2, we get

$$\overline{dim}_P \nu(x_\infty) \leq \limsup_{n \to \infty} \frac{\log \mathbb{P}\big(C^n_{\boldsymbol{x}} \cap \Omega_{\epsilon,\eta}\big)}{-\log a \ (n+1)(l-\epsilon)} \ ;$$

then using Lemma 2.1:

$$\overline{dim}_P \nu(x_\infty) \leq \limsup_{n \to \infty} \frac{-\log \mu^n(x_n)}{\log a \ (n+1)(l-\epsilon)} = \frac{h}{\log a \ (l-\epsilon)} \ .$$

This being true for each $\epsilon > 0$ on a set of measure $1 - 2\eta$ for each η, it proves the announced result. □

3 An integral formula for the rate of escape

3.1 Busemann functions

We recall the definition of Busemann functions, which we will use to estimate the rate of escape. Let σ be a geodesic ray. For each x in X, the function $t \mapsto d(x, \sigma(t)) - t$ is decreasing and bounded (it's just a consequence of the triangle inequality). So we can define the Busemann function associated to a geodesic ray σ as :

$$f_\sigma(x) = \lim_{t \to \infty} d(x, \sigma(t)) - t \ .$$

Then we define a cocycle on X^2 by :

$$\beta_\sigma(x, y) = f_\sigma(y) - f_\sigma(x) \ .$$

Remark 3.1. *Assume in addition that the space X has the following property (P) : for two equivalent rays σ_1 and σ_2, there exists T_0 such that $\lim_{t \to \infty} d(\sigma_1(t), \sigma_2(t + T_0)) = 0$. We then have, if $\sigma_1 \sim \sigma_2$,*

$$\beta_{\sigma_1}(x, y) = \beta_{\sigma_2}(x, y) \ ; \tag{8}$$

and so the function β_σ depends only on the endpoint of the ray σ. This allows us to define a cocycle on ∂X, called the Busemann cocycle, by

$$\beta_\xi(x, y) = \beta_\sigma(x, y) \ ;$$

σ being a ray with endpoint ξ.
The hyperbolic halfplane $\mathbb{H}^2$, trees, an d more generally CAT(-1) spaces have this property.

In the general case, this construction fails because if σ_1 and σ_2 have the same endpoint ξ, which means that there exists a constant D such that for all t, $d(\sigma_1(t), \sigma_2(t)) \leq D$, then the equality (8) is not satisfied but we only have

$$\left|\beta_{\sigma_1}(x,y) - \beta_{\sigma_2}(x,y)\right| \leq 2D \ .$$

However, two geodesic rays with the same point at infinity have the following property : there exists T_0 such that $\lim_{t\to\infty} d(\sigma_1(t), \sigma_2(t+T_0)) \leq 16\delta$ ([8]). This implies

Lemma 3.1. *Let* σ_1 *and* σ_2 *be two geodesic rays with the same point at infinity* ξ. *Then for any* x *and* y *in* X, *we have*

$$\left|\beta_{\sigma_1}(x,y) - \beta_{\sigma_2}(x,y)\right| \leq C_1 \ ;$$

where C_1 *is a constant relied only on* δ.

This allows us to adopt the following definition : for ξ in ∂X and x, y in X,

$$\beta_\xi(x,y) = \sup\{\beta_\sigma(x,y)\} \ ;$$

where the supremum is taken on all rays with endpoint ξ. In particular, if σ is a geodesic ray such that $\sigma(\infty) = \xi$, then

$$\left|\beta_\xi(x,y) - \beta_\sigma(x,y)\right| \leq C_1 \ . \tag{9}$$

This will not be a cocycle but we have

$$\left|\beta_\xi(x,y) - \big(\beta_\xi(x,z) + \beta_\xi(z,y)\big)\right| \leq 3C_1 \ .$$

We will need the following lemma ([3]) :

Lemma 3.2. *Let* ξ *be a point in* ∂X, σ *be a ray with endpoint* ξ, *and* x_1, x_2 *be two points in* X. *Then there exists a neighborhood* V *of* ξ *such that if* $y \in X \cap V$,

$$\left|\beta_\sigma(x_1,x_2) - \big(d(x_2,y) - d(x_1,y)\big)\right| \leq C' \ ;$$

where C' *is a constant which depends only on* δ. *In particular we have*

$$\left|\beta_\xi(x_1,x_2) - \big(d(x_2,y) - d(x_1,y)\big)\right| \leq C' + C_1 = C_2 \ .$$

Remark 3.2. *In order to estimate the rate of escape, we introduce some constants* C_i, *notation we shall keep in what follows.*

3.2 Rate of escape

We shall get a formula for the rate of escape of a random walk in term of this Busemann "quasi-cocycle". Let μ be a measure supported by a subgroup G of the group of isometries of (X,d), with a finite first moment.

Proposition 3.1. *We assume that the random walk* $(x_n o)$ *associated to* μ *converges almost surely to an element* x_∞ *in* ∂X *(which we saw is the case under hypothesis adopted in part 1.2); denote by* ν *the distribution of* x_∞. *We then have*

$$\left|l(G,\mu) - \sum_g \mu(g) \int_{\partial X} \beta_\xi(o, g^{-1}o)\, d\nu(\xi)\right| \leq C_2 \ ;$$

where C_2 *is the constant introduced in Lemma 3.2.*

Proof. Writing

$$L_n = \int d(o, x_n o) d\mathbb{P} \ ;$$

we have by definition

$$l(G, \mu) = \lim_n \frac{L_n}{n} \ .$$

So we have

$$\liminf_n (L_{n+1} - L_n) \le l(G, \mu) \le \limsup_n (L_{n+1} - L_n) \ . \tag{10}$$

Besides we have

$$\begin{aligned} L_{n+1} &= \int_G d(o, \gamma o) d\mu^{n+1}(\gamma) \\ &= \sum_g \mu(g) \int d(o, g\gamma o) d\mu^n(\gamma) \\ &= \sum_g \mu(g) \int d(o, g x_n o) d\mathbb{P} \ ; \end{aligned}$$

and so

$$\begin{aligned} L_{n+1} - L_n &= \sum_g \mu(g) \int \big(d(o, g x_n o) - d(o, x_n o) \big) d\mathbb{P} \\ &= \sum_g \mu(g) \int \big(d(g^{-1} o, x_n o) - d(o, x_n o) \big) d\mathbb{P} \ . \end{aligned}$$

The quantity $\big(d(g^{-1}o, x_n o) - d(o, x_n o)\big)$ is bounded for every n by $d(o, go)$, which is an integrable function w.r.t. $\mu \otimes \mathbb{P}$; hence we can applly the Lebesgue convergence theorem, which implies :

$$\liminf_n (L_{n+1} - L_n) \ge \sum_g \mu(g) \int \liminf_n \big(d(g^{-1}o, x_n o) - d(o, x_n o) \big) d\mathbb{P} \ .$$

Moreover Lemma 3.2 gives

$$\big| \liminf_n \big(d(g^{-1}o, x_n o) - d(o, x_n o) \big) - \beta_{x_\infty}(o, g^{-1}o) \big| \le C_2 \ ;$$

from which we deduce

$$l(G, \mu) \ge \sum_g \mu(g) \int \beta_{x_\infty}(o, g^{-1}o) d\mathbb{P} - C_2 \ .$$

We do the same for the upper limit. □

Remark 3.3. *If (X, d) has property (P) (see Remark 3.1) the previous formula is exact.*

4 Construction

In this section (X, d) is a δ-hyperbolic space, G a non-elementary subgroup of the group of isometries on X acting properly discontinuously. Our goal is to construct a random walk such that the associated h/l be arbitrarily small. For this purpose, we are going to construct a sequence (μ_k) of probability measures such that

$$\lim_{k \to \infty} \frac{h(G, \mu_k)}{l(G, \mu_k)} = 0 \ .$$

4.1 Introduction of the sequence (μ_k)

We fix a measure μ on G with a finite first moment, and such that its support generates G as a semigroup. We fix also a hyperbolic element (see the definition 1.3) γ_0 in G ; we denote $\gamma_k = \gamma_0^k o$ and $\gamma_\pm = \lim_{k\to\pm\infty} \gamma_k$. Then for each $k \geq 0$ we take

$$\mu_k = \frac{1}{2}\mu + \frac{1}{4}\left(\delta_{\gamma_0^k} + \delta_{\gamma_0^{-k}}\right) .$$

Remark that each μ_k satisfies the hypothesis of the part 1.2. We denote by ν_k the harmonic measure associated with each μ_k.

Proposition 4.1. *The quantity $h(G, \mu_k)$ is bounded by a constant which is not relied on k.*

Proof. We know that $h(G, \mu_k)$ bounded from above by $H(\mu_k)$ and we have

$$\begin{aligned} H(\mu_k) &= -\frac{1}{2}\sum_g \mu(g) \log\left(\frac{1}{2}\mu(g) + \frac{1}{4}\left(\delta_{\gamma_k}(g) + \delta_{\gamma_{-k}}(g)\right)\right) \\ &\qquad\qquad - \frac{1}{4}\log\left(\frac{1}{2}\mu(\gamma_k) + \frac{1}{4}\right) - \frac{1}{4}\log\left(\frac{1}{2}\mu(\gamma_{-k}) + \frac{1}{4}\right) \\ &\leq -\frac{1}{2}\sum_g \mu(g)\log\left(\frac{1}{2}\mu(g)\right) - \frac{1}{2}\log\left(\frac{1}{4}\right) \leq \frac{3\log 2}{2} + \frac{1}{2}H(\mu) . \end{aligned}$$

□

Hence it just remains to show that $l(G, \mu_k)$ goes to infinity. By using the formula of Proposition 3.1 we get :

$$l(G, \mu_k) \geq \sum_g \mu_k(g) \int_{\partial X} \beta_\xi(o, g^{-1}o) d\nu_k(\xi) - C_2 .$$

But

$$\begin{aligned} \sum_g \mu_k(g) \int_{\partial X} \beta_\xi(o, g^{-1}o) d\nu_k(\xi) =& \frac{1}{2}\sum_g \mu(g) \int_{\partial X} \beta_\xi(o, g^{-1}o) d\nu_k(\xi) \\ &+ \frac{1}{4}\int_{\partial X} \left[\beta_\xi(o, \gamma_k) + \beta_\xi(o, \gamma_{-k})\right] d\nu_k(\xi) ; \end{aligned}$$

and since $\left|\beta_\xi(o, g^{-1}o)\right| \leq d(o, go)$, the first element in this sum is bounded in absolute value by $L(\mu)/2$; then, writing $C_3 = C_2 + L(\mu)/2$, we get

$$l(G, \mu_k) \geq \frac{1}{4}\int_{\partial X} \left[\beta_\xi(o, \gamma_k) + \beta_\xi(o, \gamma_{-k})\right] d\nu_k(\xi) - C_3 . \tag{11}$$

We are now going to estimate the quantity in the square brackets in the previous equation.

4.2 Estimate of $\left[\beta_\xi(o, \gamma_k) + \beta_\xi(o, \gamma_{-k})\right]$

We first show a convexity inequality based on the following property of hyperbolic spaces.

Proposition 4.2. *([4]) In the δ-hyperbolic space (X, d), The metric has the following quasi-convexity property : let x_1 and x_2 be two points in X and $s : [0,1] \to X$ a constant speed parametrization of a segment joining x_1 and x_2. If y is an other point in X, then we have, for all t in $[0,1]$,*

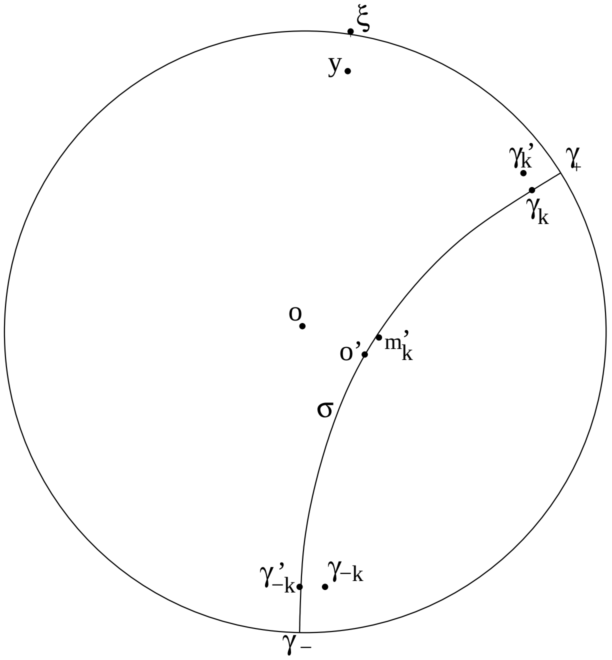
$$d(y, s(t)) \leq t d(y, x_1) + (1-t) d(y, x_2) + 4\delta .$$

We deduce the following property :

Proposition 4.3. *There exists a constant* C_4 *depending only on* δ *and* γ_0 *such that for every* $k \geq 0$ *and* $\xi \in \partial X$,

$$\beta_\xi(o,\gamma_k) + \beta_\xi(o,\gamma_{-k}) \geq -C_4 .$$

Proof. Let σ be a geodesic joining γ_+ and γ_-, K the Hausdorff distance between σ and the quasi geodesic associated with γ_0 (see Proposition 1.2). Choose o' on σ such that $d(o,o') \leq K+1$, $\gamma'_{\pm k}$ on σ such that $d(\gamma_{\pm k}, \gamma'_{\pm k}) \leq K+1$. Denote by m'_k the middle point of the segment $[\gamma'_k, \gamma'_{-k}]$. For each y in X we have



$$d(y,\gamma_k) - d(y,o) + d(y,\gamma_{-k}) - d(y,o) \geq d(y,\gamma'_k) - d(y,o') + d(y,\gamma'_{-k}) - d(y,o') - 4(K+1) \ ;$$

and

$$d(y,\gamma'_k) - d(y,o') + d(y,\gamma'_{-k}) - d(y,o') \geq d(y,\gamma'_k) + d(y,\gamma'_{-k}) - 2d(y,m'_k) - 2d(o',m'_k) \ .$$

But using the convexity property of the distance we get

$$d(y,\gamma'_k) + d(y,\gamma'_{-k}) - 2d(y,m'_k) \geq -8\delta \ ;$$

and since $d(o,\gamma_k) = d(o,\gamma_{-k})$,

$$\begin{aligned} \big|d(o',\gamma'_k) - d(o',\gamma'_{-k})\big| &= \Big|\big[d(o',\gamma'_k) - d(o,\gamma'_k) + d(o,\gamma'_k) - d(o,\gamma_k)\big] \\ &\qquad - \big[d(o',\gamma'_{-k}) - d(o,\gamma'_{-k}) + d(o,\gamma'_{-k}) - d(o,\gamma_{-k})\big]\Big| \\ &\leq 2d(o,o') + d(\gamma'_k,\gamma_k) + d(\gamma'_{-k},\gamma_{-k}) \leq 4(K+1) \ ; \end{aligned}$$

which yields

$$d(o',m'_k) \leq 2(K+1) \ .$$

So we get

$$d(y,\gamma_k) - d(y,o) + d(y,\gamma_{-k}) - d(y,o) \geq -4(K+1) - 8\delta - 4(K+1) \ ;$$

and using Lemma 3.2 allows us to conclude, denoting $8(K+1) + 8\delta + C_2$ by C_4. □

We are now going to show that on a "big enough" set (w.r.t. the measures ν_k) of the boundary, $\big[\beta_\xi(o,\gamma_k)+\beta_\xi(o,\gamma_{-k})\big]$ goes to $+\infty$ when k does.
We have, if y is in a neigbourhood of ξ, again using Lemma 3.2,

$$\beta_\xi(o,\gamma_k)+\beta_\xi(o,\gamma_{-k}) \geq d(y,\gamma_k)-d(y,o)+d(y,\gamma_{-k})-d(y,o)-C_2\ ;$$

hence

$$\beta_\xi(o,\gamma_k)+\beta_\xi(o,\gamma_{-k}) \geq d(o,\gamma_k)+d(o,\gamma_{-k})-2(y|\gamma_k)-2(y|\gamma_{-k})-C_2\ ; \tag{12}$$

so if the two Gromov products in this sum are bounded(which is the case if $\xi \notin \{\gamma_+,\gamma_-\}$), we then have

$$\lim_{k\to\infty} \beta_\xi(o,\gamma_k)+\beta_\xi(o,\gamma_{-k}) = +\infty\ .$$

However, in order to conclude using formula (11), we need that the quantity $\big[\beta_\xi(o,\gamma_k)+\beta_\xi(o,\gamma_{-k})\big]$ goes to infinity uniformly on a set whose ν_k-measure remains greater than a strictly positive constant.

Lemma 4.1. *Let U be a neigbourhood of γ_+ in ∂X. Then there exists a constant $C>0$ and an integer K such that for every $k\geq K$ and every $\xi\notin U$*

$$(\xi|\gamma_k)\leq C\ .$$

Proof. We saw that the topology on ∂X was defined by neighborhoods of the type $\{\xi' : (\xi|\xi')\geq D'\}$. Let C' be a constant such that if $(\xi|\gamma_+)\geq C'$, then $\xi\in U$. Take a K such that if $k\geq K$, then $(\gamma_k|\gamma_+)\geq C'+\delta$. Let then be $\xi\notin U$; if we had $(\gamma_k|\xi)\geq C'+\delta$, we would have

$$(\xi|\gamma_+)\geq \min\big\{(\gamma_k|\gamma_+),(\gamma_k|\xi)\big\}-\delta\geq C'\ ;$$

so we deduce the result taking $C=C'+\delta$. □

We saw in Proposition 1.1 how to show that the harmonic measure of an open set was strictly positive by using the minimality of the limit set through Proposition 1.5. We are now going to show in the same way that we can bound from below uniformly w.r.t. k the ν_k-measure of an open set.

Proposition 4.4. *Let U be an open set meeting Λ. There exist a constant $\alpha>0$ (relied on U and μ) such that for every k,*

$$\nu_k(U)\geq\alpha\ .$$

Proof. We take $\gamma_1,\cdots,\gamma_r\in G$ like in Proposition 1.5 :

$$\Lambda\subset\bigcup_{1\leq i\leq r}\gamma_i U\ ;$$

and s such that $\gamma_1,\cdots,\gamma_r\in supp(\mu^s)$. Now we remark the following : we have a sort of uniform stationnarity of the ν_k. Indeed as $\nu_k=\mu_k*\nu_k$ and for every k $\mu_k\geq 1/2\mu$,we have

$$\nu_k\geq\frac{1}{2^s}\mu^s*\nu_k\ ;$$

and so

$$\begin{aligned}\nu_k(U)&\geq\frac{1}{2^s}\sum_{g\in supp(\mu^s)}\mu^s(g)\nu_k(gU)\\&\geq\frac{1}{2^s}\sum_i\mu^s(\gamma_i)\nu_k(\gamma_iU)\\&\geq\frac{1}{2^s}\min_i\mu^s(\gamma_i)\ .\end{aligned}$$

□

Since G is assumed to be non-elementary, Λ contains an element wich is distinct from γ_+ and γ_- ; so we can fix an open set U meeting Λ and which doesn't contains γ_+ neither γ_-. Using Lemma 4.1 with $\partial X \setminus U$ as a neighborhood of γ_+ (and γ_-), we take C_5 and K such that if $\xi \in U$ and $k \geq K$,

$$(\xi|\gamma_{\pm k}) \leq C_5 \ .$$

Using formula (12), we get, for $k \geq K$ and $\xi \in U$:

$$\beta_\xi(o, \gamma_k) + \beta_\xi(o, \gamma_{-k}) \geq 2d(o, \gamma_k) - 4C_5 - C_2 \ .$$

Besides formula (11) and Proposition 4.3 give us

$$l(G, \mu_k) \geq \frac{1}{4} \int_U \left[\beta_\xi(o, \gamma_k) + \beta_\xi(o, \gamma_{-k})\right] d\nu_k(\xi) - \frac{C_4}{4} + C_3 \ ;$$

and now we use the previous proposition to get

$$l(G, \mu_k) \geq \frac{\alpha}{4}\left[2d(o, \gamma_k) - 4C_5 - C_2\right] - \frac{C_4}{4} - C_3 \ .$$

Since the first element of the right member in previous equation goes to infinity, this gives us :

Proposition 4.5. *With the notations previously adopted,*

$$\lim_{k \to \infty} \frac{h(G, \mu_k)}{l(G, \mu_k)} = 0 \ .$$

5 Main result

Putting together Proposition 4.5 of the previous section and Proposition 2.1 of section 2, we get the following result :

Theorem 5.1. *Let G be a subgroup of the group of isometries of a hyperbolic space (X, d) acting properly discontinuously and which is not elementary. For every $\epsilon > 0$ there exists on G a symmetric probability measure μ with a finite first moment, whose support generates G, and which has the following property: the pointwise dimension of the harmonic measure ν associated with (G, μ) is ν-almost surely smaller than ϵ.*

Now we restrict ourself to the case where (X, d) is the Cayley graph of G. In this case, in view of Propositions 1.7 and 1.1, Theorem 5.1 implies that the Hausdorff dimension of the harmonic measure can be strictly lower than the dimension of the boundary, whose value is $e_a(G)$. And in view of Remark 1.1, it implies that the harmonic and Hausdorff measures are not equivalent; since both are ergodic they are singular. So we get the following result on the type of the harmonic measure :

Corollary 5.1. *In the case where X is the Cayley graph of a hyperbolic group G, there exist on G a symmetric probability measure μ with a finite first moment, whose support generates G, and such that the associated harmonic measure and the Hausdorff measure on ∂G are mutually singular.*

Let us finally note that concerning the asymptotic behaviour of the sequence (ν_k), we can prove that for every subsequence of (ν_k) which converges weakly to a certain measure ν, all points of the orbit of γ_+ and γ_- under G are atoms for ν. In the case of a finitely generated free group, the sequence (ν_k) even converges weakly to an atomic measure suported by the orbit of γ_+ and γ_- under G.

Acknowledgments. I would like to thank my supervisor Vadim Kaimanovich for his advices during the redaction of this paper.
